booksTransforming growth factor-beta regulation of osteoblast-
differentiated human mesenchymal stem cells. Transforming
growth factor-beta (TGF-beta) is believed to play a major role
in the control of osteoblastogenesis in bone. Mesenchymal stem
cells (MSC) have emerged as an important population of cells
able to support long-term hematopoietic stem cell self-renewal.
They can also differentiate along various mesenchymal lineages
including osteoblasts. We investigated the effect of TGF-beta
on growth and differentiation of human MSC, namely
pluripotent mesenchymal stem cells and multipotent
osteoprogenitor cells, and demonstrate that TGF-beta1
preferentially stimulates growth and osteogenic differentiation
of the osteoprogenitor fraction, and inhibits their proliferation.

The response was time- and dose-dependent. Treatment of these cells with TGF-beta1 for 4 days induced Smad2 and Smad3 phosphorylation, while Smad1 phosphorylation was weak and Smad4 was absent. Transcriptional analysis of TGF-beta target genes showed that TGF-beta1 upregulated expression of osteocalcin and bone sialoprotein in the osteoprogenitor fraction and inhibited expression of the MSC-specific genes, Osterix, osteocalcin, and alkaline phosphatase. This effect was also observed at the transcriptional level with transient transfection of the osteoprogenitor cells with an osteocalcin promoter construct linked to a luciferase reporter gene. This study demonstrates that the differential effects of TGF-beta on human MSC are both direct and indirect through gene regulation. These findings provide a molecular explanation for the preferential effect of TGF-beta on osteogenesis and suggest that MSC may have a dual role in bone repair.12% Show Thriving Despite Depression It seems

This is not likely to be the outcome of prairie dog conservation, because the conditions of the prairie dog habitat are unlikely to remain the same. The characteristic prairie dog habitat is a permanent valley surrounded by mountains. Once the environment is made static, the population cannot adapt to, or maintain, a self-sustaining population. It is likely that the humans that turned the prairie dog into a hunted species will return. The prairie dog has become the proverbial canary in the coal mine.
